Abstract. Over-expression of *ERBB2*, a member of the family of transmembrane receptor tyrosine kinases, occurs in 15-30% of primary breast tumors and is associated with poor prognosis and chemoresistance to a variety of anticancer drugs. In this study, aiming to identify differentially-expressed genes involved in erbB2-mediated transformation of the breast, we generated SAGE libraries from two human mammary cell lines, derived from normal luminal cells, expressing different levels of erbB2. The parental cell line HB4a expresses basal levels and the C5.2 expresses high levels of erbB2. A total of 161,632 tags was generated by sequencing, 81,684 from HB4a cells (30,854 unique tags) and 79,948 from C5.2 cells (30,568 unique tags). The comparison between the HB4a and C5.2 libraries revealed 334 distinct transcripts more expressed in HB4a cells and 328 distinct transcripts more expressed in C5.2 cells. The expression pattern of some of these transcripts was further validated by RT-PCR. The C5.2 cell line, which over-express *ERBB2*, showed in comparison to HB4a cells a higher percentage of genes involved in transport, RNA processing, apoptosis and protein folding. A higher percentage of the genes more expressed in HB4a cells compared to C5.2 were found to be involved in signal transduction and cytoskeleton organization. The use of SAGE analysis allowed us to identify a significant number of genes implicated in different cellular pathways up- or down-regulated in the presence of *ERBB2* over-expression, including genes not previously implicated in breast cancer that could be considered as potential candidate markers for prognosis and therapy.

Introduction

The *ERBB2* gene, also known as HER2/NEU, encodes a 185-kDa transmembrane glycoprotein with intrinsic tyrosine kinase activity that belongs to the epidermal growth factor receptor (EGFR) family (1). This family of receptor tyrosine kinases (RTKs) comprises four members, *EGFR* (*ERBB1*), *ERBB2* (*HER2*), *ERBB3* and *ERBB4* that play important roles in several signal transduction pathways regulating cell proliferation, differentiation, cytoskeletal rearrangement and survival (1,2). The RTKs are cell surface allosteric enzymes activated by the ligand-binding that induces receptor monomers to form homo- or heterodimers. Receptor dimerization induces auto-phosphorylation on tyrosine residues creating binding sites for several adaptor proteins and enzymes, such as Grb2 and Shc, leading to the activation of intracellular signal transduction that includes Ras/Raf/mitogen-activated protein kinase (MAPK) and phosphatidylinositol-3 kinase (PI-3K) pathways (3,4). Although no specific ligand for *ERBB2* has been identified it is believed to play a key role in the *EGFR* family signaling since *ERBB2* is the preferred and more effective heterodimerization partner for all other family members (5,6).

Clinical and experimental evidence indicates that *ERBB2* over-expression plays important role in the malignant transformation, tumorigenesis and metastasis, however the mechanisms or *ERBB2* target genes involved are not fully known. In breast cancer, *ERBB2* over-expression usually due to gene amplification has been shown to occur in 15-30% of invasive ductal tumors, where it correlates with patient poor prognosis and resistance to hormone- and chemotherapy (7,8). Induced over-expression of *ERBB2* increases tumorigenic and metastatic potential of breast cancer cells and transgenic mice that over-express *ERBB2* display high incidence of mammary tumors and metastasis (9,10). Both *in vitro* and *in vivo* experimental results demonstrated that tyrosine kinase inhibitors, anti-sense oligonucleotides, monoclonal antibodies and siRNA are able to abolish the effects of *ERBB2* gene in mammary tumorigenesis (11,12). Therefore, *ERBB2* also proved to be an excellent target for therapeutic approaches. One example is the humanized antibody for erbB2 called Herceptin, approved for clinical application, has been successfully used for the treatment of breast cancer patients,

Key words: breast cancer, SAGE, *ERBB2*, gene expression

both alone or in combination with other chemotherapeutic regimens (13,14).

Up-regulation of cyclin D1 and down-regulation of p27^{kip1} has been shown to be associated with cell proliferation and survival during *ERBB2* malignant transformation (15,16). Mammary tumors from transgenic mice that over-express *ERBB2* under the control of the endogenous promoter show up-regulation of several transcriptional factors associated with the differentiation status of the tumors (17). In fact, gene expression changes in response to *ERBB2* over-expression may have a significant impact on several biological processes, such as proliferation, differentiation, cell adhesion, apoptosis and angiogenesis.

The identification of *ERBB2* target genes could provide additional insights into the malignant transformation and contribute to improve diagnosis, prognosis and treatment of breast cancer. Differential cDNA hybridization and cDNA microarray techniques have been successfully used to identify differentially-expressed genes in breast cancer cells and tumors (18-22). In the present study, aiming to identify additional *ERBB2* target genes, we generated SAGE libraries from two human mammary cell lines, HB4 and C5.2, expressing different levels of *ERBB2* (23). Consistent with the role played by *ERBB2* signaling in behavior of mammary epithelial cells and tumors, using this approach we were able to identify potential *ERBB2* target genes implicated in a variety of cellular processes including cell proliferation, apoptosis and cytoskeleton organization.

Materials and methods

Cell culture. The mammary cell lines HB4a, C3.6 and C5.2 were kindly provided by Dr Michael O'Hare from Ludwig Institute for Cancer Research, London, UK. The parental HB4a is a normal mammary luminal epithelial cell line established as previously described (24). C3.6 and C5.2 cell lines were obtained by the transfection of HB4a cells with full-length normal human *ERBB2* cDNA derived from the breast cancer cell line BT474 (23). These cells were cultured in RPMI-1640 supplemented with 10% FCS, 2 mM glutamine, 100 IU/ml penicillin, 100 µg/ml streptomycin and 5 µg/ml hydrocortisone and insulin in a 5% CO₂ humidifier incubator at 37°C.

RNA extraction. For total RNA extraction the cells were washed twice with PBS, harvested and homogenized in a solution containing guanidine isothiocyanate (4 M guanidine isothiocyanate, 25 mM sodium citrate pH 7.0, 0.5% sarcosyl and 100 mM β-mercaptoethanol) and extracted as described (25). The quality of the RNA samples was determined by 1% agarose gel electrophoresis and ethidium bromide staining. All RNA samples were treated with DNase I for 1 h at 37°C to eliminate genomic DNA contamination.

Serial analysis of gene expression (SAGE). Total RNA (25 µg) isolated from HB4a and C5.2 cell lines were used to generate SAGE libraries. SAGE was carried out using the I-SAGE kit (Invitrogen) according to the manufacturer's protocol based on the original SAGE method (26). Concatemerized ditags were cloned into pZERO-1 and the amplified inserts were sequenced using ET Dye Terminator Kit (Amersham Bio-

Table I. Summary of SAGE analysis in human mammary luminal cells HB4a and C5.2.

	HB4a	C5.2
Total no. of tags	81,684	79,948
Unique tags	30,854	30,568
Annotated tags	19,314	19,181
Tag-gene	7,698	7,616

sciences) and forward M13 primer and analyzed with a Mega BACE 1000 automated sequencer (Amersham Biosciences). Tag frequency tables were obtained from sequences by SAGE™ analysis software, with minimum tag count set to one, maximum ditag length set to 28, and other parameters set as default. The annotation was based on two specific tools, SAGEmap (<http://www.ncbi.nlm.nih.gov/SAGE>) and CGAP SAGE Genie (<http://cgap.ncbi.nih.gov/SAGE>).

Semi-quantitative RT-PCR. Total RNA (10 µg) was reverse-transcribed using the High Capacity cDNA Archive kit (Applied Biosystems). PCR amplification was performed in 25 µl volume using 50 ng of cDNA, 0.6 µM of each primer, 1.5 mM MgCl₂, 125 µM of each deoxynucleotide triphosphate, 50 mM KCl, 10 mM Tris-HCl pH 8.0, and 0.2 unit of *Taq* DNA polymerase (Invitrogen, Carlsbad, USA) and consisted of 28 and 32 cycles of denaturation for 30 sec at 94°C, annealing for 1 min at 55°C and extension for 1 min at 72°C, followed an extension of 5 min at 72°C. The expression of glyceraldehyde-3-phosphate dehydrogenase (*GAPD*) gene was used as an internal control for cDNA input. The PCR products were separated by electrophoresis on 2% agarose gels stained by ethidium bromide.

Results

Aiming to identify genes involved in erbB2-mediated transformation of the breast we compared the gene expression profiles of two human mammary luminal epithelial cell lines expressing different levels of erbB2 using SAGE technique. Two independent SAGE libraries were constructed from HB4a (the parental cell line showing basal expression levels of erbB2) and C5.2 (showing high expression of erbB2) cell lines.

A total of 161,632 tags was generated by sequencing, 81,684 tags derived from HB4a and 79,948 derived from C5.2 cell lines (Table I). Excluding redundancy the sequence analysis identified 30,854 and 30,568 distinct tags from HB4a and C5.2 cells, respectively. In HB4a SAGE library, 19,314 from 30,854 unique tags correspond to UniGene clusters representing known genes, hypothetical proteins and expressed sequence tags (ESTs), the remaining 11,540 tags showed no matches in the CGAP SAGE Genie. In HB4a SAGE library, 19,181 from 30,568 unique tags correspond to UniGene clusters representing known genes, hypothetical proteins and expressed sequence tags (ESTs), the remaining 11,387 tags showed no matches in the CGAP SAGE Genie.

The comparison between the two SAGE libraries was performed using the tools found in our website (<http://gdm>.

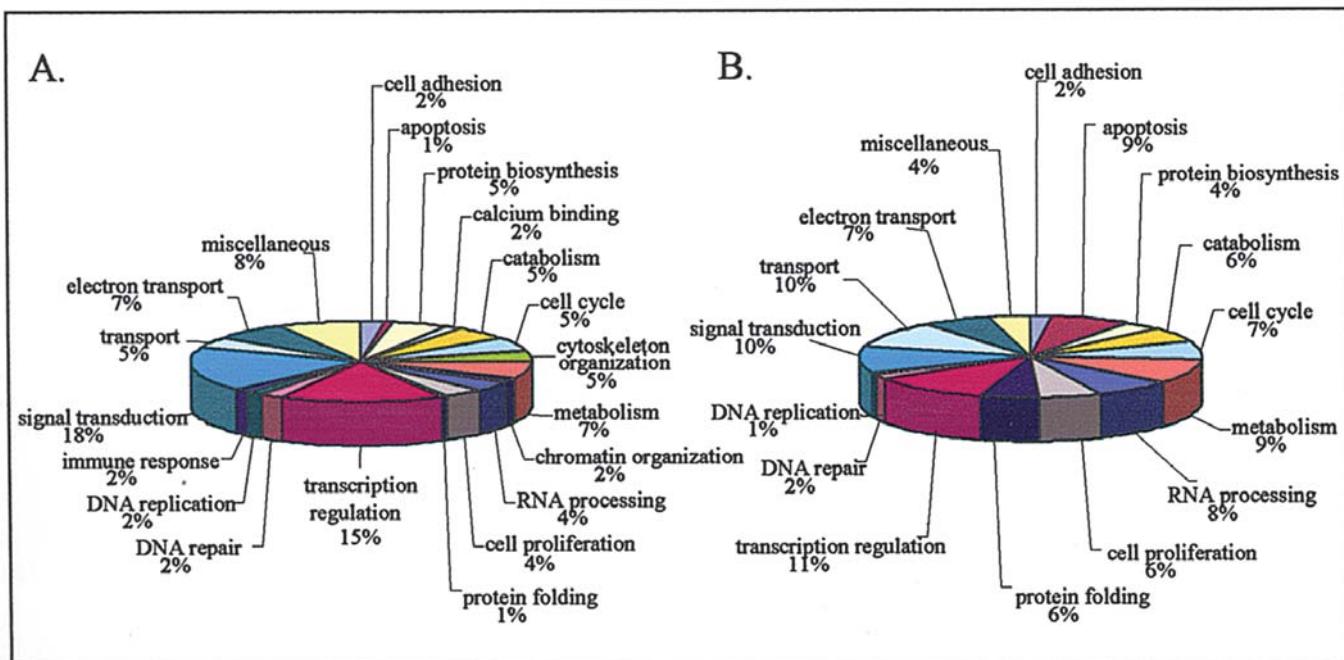

Figure 1. Distribution of the more expressed transcripts from HB4a (A) and C5.2 (B) cell lines classified by functional categories using Gene Ontology nomenclature.

fmrp.usp.br/cgi-bin/gc/uploadFace.pl). Using a cut-off at ≥ 4 -fold changes between the transcripts from HB4a and C5.2 libraries we detected 334 distinct genes more expressed in HB4a and 328 distinct genes more expressed in C5.2. The list of the 50 most expressed genes in the HB4a and C5.2 cells is shown in Tables II and III, respectively. A complete list of the differentially-expressed genes (cut-off ≥ 4 -fold changes) are shown as supplementary Tables II and III). Public available databases (e.g. Gene Ontology, Locus Link, UniGene cluster) were used to annotate by biological function the genes more expressed in each cell line. No functional roles could be assigned for 70 (21%) of the transcripts more expressed in HB4a cells and 95 (29%) of the transcripts more expressed in C5.2. The majority of the other transcripts could be classified using Gene Ontology nomenclature (Fig. 1). C5.2 cell line, which over-expressed the erbB2 gene, showed in comparison to HB4a cells a higher percentage of genes involved in apoptosis (C5.2, 9% vs. HB4a, 1%), transport (C5.2, 10% vs. HB4a, 5%), RNA processing (C5.2, 8% vs. HB4a, 4%) and protein folding (C5.2, 6% vs. HB4a, 1%). A higher percentage of the genes more expressed in HB4a cells compared to C5.2 were found to be involved in signal transduction (HB4a, 18% vs. C5.2, 10%) and cytoskeleton organization (HB4a, 5% vs. C5.2, 0%).

Based on tag abundance and functional annotation, 9 of the differentially-expressed genes were selected for validation by RT-PCR. Those included 5 genes up-regulated (*MATR3*, *MGC11242*, *HDGF*, *CENPH* and *ANP32B*) and 4 down-regulated (*ETFB*, *RUVBL1*, *SPARC* and *SFRP1*) in C5.2 as compared to HB4a cells. The cell line C3.6, which shows moderate expression of the erbB2 gene, was also included in the validation analysis. The expression pattern of the 9 genes selected from SAGE technique was confirmed by RT-PCR analysis (Fig. 2).

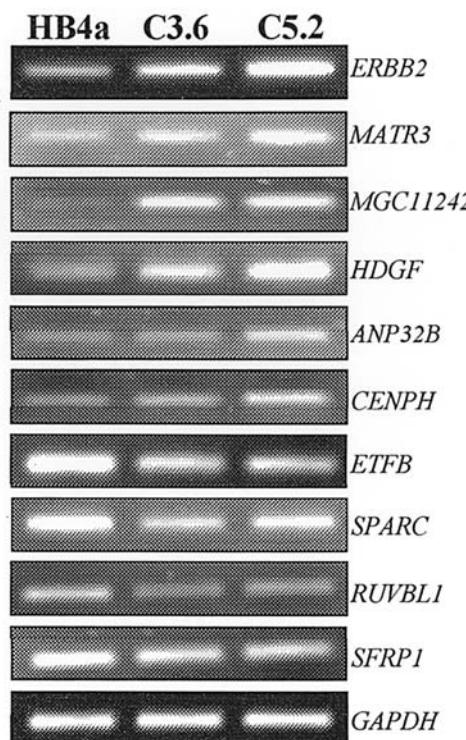

Figure 2. Validation by RT-PCR analysis of 9 differentially-expressed genes from HB4a and C5.2 SAGE libraries.

Discussion

ERBB2 over-expression activates important cell signaling pathways including ras/raf/MAPK and PI3K/AKT leading to the activation and repression of downstream genes especially involved in cell proliferation and survival implicated in

malignant transformation. Transgenic mice over-expressing *ERBB2* develop mammary tumors with high incidence and *ERBB2* over-expression has been demonstrated in 15-30% of human breast cancer in association with poor prognosis and resistance to hormone- and chemotherapy (1,27). The identification of *ERBB2* target genes may provide new insights into the tumorigenic process of the breast that could also have impact on diagnosis, prognosis and treatment of the disease.

In the present study, we used serial analysis of gene expression (SAGE) to characterize the transcriptome of two human mammary epithelial cell lines expressing different levels of *ERBB2* and to identify *ERBB2* regulated genes. The SAGE technique offers the opportunity of both high-throughput and quantitative analysis of gene expression profiles of a cell or tissue including known as well as unknown genes. The use of SAGE approach has enabled us to confirm previous data reported by others and to extend the number of new candidate genes up- or down-regulated by *ERBB2* in human mammary cells. Comparison of our SAGE results with the data reported by Mackay *et al* (20) in the same cell lines (HB4a and C5.2) but using a cDNA microarray containing 6,000 different transcripts showed many similarities. Not all, but several of the 61 transcripts identified by these authors as up-regulated, such as *LGALS1*, *CRIPI*, *S100P*, *MGC11242*, *SQLIE*, *HSPB1*, *DNAJB6* or down-regulated, such as *MYL9*, *SPARC*, *FNI*, *TAGLN*, *SPINT2*, *GTF3B*, *PMSD8* in the C5.2 cell line, which expresses high levels of *ERBB2*, showed the same pattern in our SAGE libraries, indicating that both platforms, cDNA microarrays and SAGE, are very sensitive methods to determine gene expression profiling. However, the use of SAGE technique allowed us to identify a large number of transcripts not previously identified as *ERBB2* regulated genes including those with unknown function. The relative abundance of the differentially-expressed transcripts in our SAGE libraries was validated by RT-PCR analysis. All nine genes analyzed by RT-PCR displayed the same expression pattern observed in the SAGE analysis, such as *MATR3*, *MGC11242*, *HDGF*, *ANP32B* and *CENPH* found to be up-regulated and *ETFB*, *SPARC*, *RUVBL1* and *SFRP1* found to be down-regulated in cells over-expressing *ERBB2*. However, the differences in the transcript levels were more evident in SAGE libraries, this lack of complete concordance could be due to the lower sensitivity of semi-quantitative RT-PCR to detect transcript abundance.

The malignant transformation involves changes in cell proliferation and survival, cell shape and cytoskeleton and alterations of cell adhesion. Several lines of evidence have implicated *ERBB2* in cell proliferation, differentiation and apoptosis. We further divided the most up-regulated and down-regulated genes into functional categories. Over-expression of *ERBB2* affected the expression of genes involved in different biological processes. Interestingly, the C5.2 cell line that over-express *ERBB2* showed a higher percentage of genes involved in cell cycle/proliferation, apoptosis and protein folding and lower percentage of genes involved in cytoskeleton organization than HB4a cell line.

A higher number of apoptosis-related genes were observed in the C5.2 library than in the HB4a library. Most of these genes (*PBP*, *PDCD4*, *ANP32B*, *BTG1*, *BNIPI*) play pro-apoptotic activity and show elevated expression probably in

response to the oncogenic stress experienced by the C5.2 cells. However, the ability of these genes to sensitize C5.2 cells to apoptosis is possible overcome by *ERBB2* over-expression that evokes activation of the PI3K and AKT and promotes cellular survival (28,29). Active PBK/AKT has been shown to protect against apoptosis through phosphorylation and inhibition of proapoptotic proteins such as Bad and Foxo (30-32). However, if this is the case, the proapoptotic genes identified here requires further experimental studies.

In our SAGE analysis, several genes encoding for chaperone and co-chaperone proteins such as Hsp90, Hsp70, Hsp40 and Hsp27 were detected as up-regulated in the C5.2 cell line, which over-express *ERBB2*. Heat shock proteins are an important family of endogenous protective proteins expressed in all tissues and induced under various stresses and different signals (33). Hsp70 and Hsp90 participate in the folding of numerous proteins including oncoproteins and also play critical roles in maintaining the estrogen receptor conformation for proper ligand binding (34,35). High expression of Hsp90, Hsp70 and Hsp27 in human tumors, including breast cancer, is correlated with poor prognosis and therapy resistance (36). Furthermore, those heat shock proteins have anti-apoptotic functions. The chaperone Hsp90 has been shown to stabilize anti-apoptotic proteins such as survivin and *RIP* and to inhibit pro-apoptotic kinase ASK1 (apoptosis signal regulator kinase 1) (37-39). Moreover, inhibition of Hsp90 by geldanamycin induces growth arrest and apoptosis in cells over-expressing *ERBB2* (40,41). Depletion of Hsp70 induces massive cell death in different tumorigenic cell lines revealing its anti-apoptotic function (42,43). There is also evidence showing that Hsp27 display anti-apoptotic activity. Hsp27 expression protects from apoptosis induced by TNF- α and chemically-induced cell death (44,45). Although the differential expression pattern of chaperone protein observed here could reflect the cellular adaptation to several types of stress, these differences may in part account for the increased cell survival and drug resistance associated with *ERBB2* over-expression.

Altered cytoskeleton organization is a hallmark of transformed cells, which acquire a more rounded shape and increased cell invasive and metastatic potential. In our SAGE analysis we identified down-regulation of genes associated with cytoskeleton organization such as *ACTN1* and *TPM1*. This finding is consistent with the disorganized and irregular shape displayed by the cell line C5.2 on Matrigel in comparison to the parental cell line HB4a (23). The role played by the *ACTN1* in cancer is unclear. The *ACTN1* encodes for a member of the α -actinin family that bind actin and play a key role in the assembly and maintenance of stress fibers in non-muscle cells (46,47). α -actinin 1 is believed to link actin cytoskeleton to adhesion plaques via integrins and other actin-binding proteins (48-50). The expression of α -actinin 1 has also been found to be down-regulated in SV40-transformed NIH3T3 cells (51), indicating that loss of α -actinin 1 may play a role in malignant transformation. A recent study showed that erbB2 induces integrin inactivation in breast cancer cells through actin cytoskeletal rearrangement dependent on PI3K and PKB pathways (52).

Tropomyosin 1 (TPM1) one of the genes found to be down-regulated in the cell line with *ERBB2* over-expression

is a member of a family of actin binding proteins that play important function in microfilament stabilization (53,54). *TPM1* expression is down-regulated in several transformed cells, including breast cancer cells (54-56) and restoration of its expression is able to revert the malignant phenotype of oncogene-transformed cells (57). Primary breast tumors express low or undetectable levels of *TPM1* (58). In fact, *TPM1* has been shown to suppress the malignant phenotype of breast cancer cells. Restoration of *TPM1* expression in MCF-7 cells decreases cell proliferation, inhibits anchorage-independent growth and alters interaction of E-cadherin-catenin complex contributing to the stability of cell-cell adherens junctions (59). Down-regulation of both *ACTN1* and *TPM1* expression could be a result of the activation of ERBB2 signaling pathways that induces actin reorganization and motility, enhances the invasiveness and metastatic potential and chemoresistance of cancer cells (60).

Using serial analysis of gene expression (SAGE), we identified a large number of differentially-expressed genes in human mammary epithelial cells over-expressing *ERBB2* that are associated with different biological processes. Several of these genes are new or hypothetical proteins not previously implicated in breast cancer. Although, further experimental and clinical studies are required, some of these genes could be considered as potential candidate markers of the aggressive phenotype displayed by breast tumors over-expressing *ERBB2* and potential therapeutic targets of the disease.
