Abstract. Osteosarcoma is the most common primary malignant bone tumor. Cancer cells employ a host of mechanisms to develop resistance to adriamycin (ADM) or other chemotherapeutic drugs. Shikonin (SK), an active constituent extracted from a Chinese medicinal herb, has been shown to cooperate with ADM in the treatment of osteosarcoma and certain other types of cancer by contributing to the response rate of chemotherapy and the side effects. The aim of the present study was to investigate the role and underlying mechanism of SK in chemotherapy for osteosarcoma. In the present study, a CCK-8 assay was performed to assess cell survival rate in vitro. Western blot analysis was performed to determine the expression levels of B-cell lymphoma 2-associated X protein (Bax), caspase-3, caspase-8, and poly (ADP-ribose) polymerase (PARP). Flow cytometry was used to analyze cell cycle and cell death. The survival rate of cells decreased significantly in a dose- and time-dependent manner when treated with a combination of SK and ADM. Western blot analysis revealed increased expression levels of Bax, caspase-3, caspase-8 and PARP in U2OS and MG63 cells 48 h following treatment with SK and ADM. Flow cytometric analysis showed that the combined treatment of SK and ADM significantly induced apoptosis in the osteosarcoma cells. Taken together SK cooperated with ADM

to promote apoptosis, possibly by inducing caspase-3- and caspase-8-dependent apoptosis. SK may be a potential enhancer in the treatment of drug-resistant primary osteosarcoma.

Introduction

Osteosarcoma is the most common primary malignant bone tumor, which accounts for $\sim\!60\%$ of all bone sarcomas (1,2). The introduction of chemotherapy has led to a marked improvement in the prognosis of patients with localized osteosarcoma. Long-term survival rates, previously <20%, have improved to 65-70% following the advent of multiagent chemotherapy regimens (3). However, the survival rate for patients with osteosarcoma remains low. A significant proportion of osteosarcomas cases are not sensitive to conventional chemotherapy, with long-term survival rates of $\sim\!20\%$ (4).

Adriamycin (ADM) is one of the most widely used chemotherapeutic drugs for the treatment of human osteosarcoma. However, the acquisition of ADM resistance is common in patients with osteosarcoma, leading to local and distant failure. In addition, high doses of ADM lead to toxic side effects in patients with osteosarcoma (5,6). Therefore, an alternative strategy is required, which enables a decrease in the dose of chemotherapeutics required, but enhances the sensitivity of cancer cells to chemotherapeutics.

Natural products are important in cancer chemotherapy due to their beneficial pharmacological activities and low toxicity. Tumor therapy with traditional Chinese herbs, including curcumin (7-9), triptolide (10) and Danshen (11) is becoming increasingly attractive (12). Shikonin (SK), an effective constituent purified from the Chinese medicinal herb, *Lithospermum erythrorhixon*, has been shown to exert antitumor effects by inhibiting pyruvate kinase-M2 (PKM2). PKM2, which catalyzes the final rate-limiting step in glycolysis, is vital for cancer cell proliferation and is universally overexpressed in cancer cells (13). SK was previously shown to be a cytotoxic DNA-binding agent (14). Furthermore, SK and its analogs have been shown to induce minimal cancer drug resistance (15).

To decrease the side effects and enhance the efficacy of traditional Chinese medicines, different combinations of medicinal herbs have been used as an alternative strategy for cancer therapy. The present study aimed to analyze the *in vitro* effects of the combination treatment of SK and ADM on human osteosarcoma cell lines.

Materials and methods

Cell lines and cell culture. The U2OS and MG63 human osteosarcoma cell lines were obtained from American Type Culture Collection (Manassas, VA, USA). All cells were cultured in high glucose Dulbecco's modified Eagle's medium (DMEM-h) supplemented with 10% fetal bovine serum (FBS), 100 U/ml penicillin and 100 μ g/ml streptomycin (all from Thermo Fisher Scientific, Inc., Waltham, MA, USA) in a humidified incubator at 37°C in 5% CO₂.

Drugs and antibodies. Purified SK (>98%) was purchased from Shanghai Tauto Biotech Co., Ltd. (Shanghai, China). ADM (5 mmol/l) was purchased from Selleck Chemicals (Houston, TX, USA). Stock solutions were produced in dimethyl sulfoxide (Sigma-Aldrich; Merck Millipore, Darmstadt, Germany) at a concentration of 50 mM and stored in the dark at -20°C. SK and ADM were used at final concentrations of 0.01 and 0.1 μ M, respectively, by diluting the stock solution in DMEM-h. The antibodies used for western blot analysis were as follows: Rabbit anti-actin (Santa Cruz Biotechnology, Inc., Dallas, TX, USA; cat no. sc130657), anti-B-cell lymphoma 2-associated X protein (Bax; cat no. ab7977), anti-caspase-3 (cat no. 9664), anti-caspase-8 (cat no. ca0689), and anti-poly (ADP-ribose) polymerase (PARP; cat no. 9542) (all from Cell Signaling Technology, Inc., Danvers, MA, USA).

CCK-8 assay. The U2OS and MG63 osteosarcoma cells $(0.5 \times 10^4/\text{well})$ were seeded into 96-well plates and cultured overnight for adherence of cells. The cells were then treated with SK $(0.01~\mu\text{M})$, ADM $(0.1~\mu\text{M})$ or a combination of SK $(0.01~\mu\text{M})$ and ADM $(0.1~\mu\text{M})$ for 48 h at 37°C. Cells incubated with DMEM-h were used as a control group. Following incubation for 48 h, the supernatant was removed and 2 ml CCK-8 (Beyotime Institute of Biotechnology, Shanghai, China) was added into each well and incubated for 1 h to solubilize the blue-purple crystals of formazan. The absorbance was then measured at 490 nm using an ELX800 microplate reader (BioTek Instruments, Inc., Winooski, VT, USA). The survival rate was calculated according to the following formula: Survival rate = absorbance of treatment/absorbance of control x100%.

Flow cytometric analysis. The U2OS and MG63 osteosarcoma cells ($2x10^5$ /well) were plated in 6-well plates and synchronized with DMEM-h containing 10% FBS. Following incubation for 8 h, the SK-treated cells (0.01 μ M), ADM-treated cells (0.1 μ M) and combination treated-cells were treated with 0.01 μ M SK and 0.1 μ M ADM for 48 h at 37°C. The cells were then collected and washed twice in cold PBS. The cells were mixed in 100 μ l of 1X binding buffer and incubated at room temperature for 15 min with Annexin-V/7AAD (eBioscience, Inc., San Diego, CA, USA) double staining solution. The stained cells were analyzed using flow cytometry. The percentages of necrotic cells and the proportions of cells in different cell cycle stages were calculated using BD Accuri C6

software (C Flow Sampler Analysis version 1.0.208.2 Installer; BD Biosciences, San Jose, CA, USA).

Western blot analysis. The U2OS and MG63 cells were treated with the different solutions (DMEM-h, SK, ADM, or a combination of SK and ADM) for 48 h. The cells were then washed twice with PBS solution and lysed in RIPA lysis buffer (Beyotime Institute of Biotechnology) containing protease inhibitors (Thermo Fisher Scientific, Inc.). The tumor cells were retrieved from -80°C storage and immersed rapidly in liquid nitrogen. The resulting powder was lysed in RIPA lysis buffer containing protease inhibitors. Protein concentrations were determined using a Pierce BCA protein assay kit (Thermo Fisher Scientific, Inc.). Equivalent quantities of total protein (50 µg) were boiled and electrophoretically separated on a 10% polyacrylamide gel at 80 volts. The proteins were then transferred onto a nitrocellulose filter membrane. The membranes were blocked for 60 min with a 5% milk solution prepared in PBS, and then incubated overnight at 4°C with a 1:1,000 dilution of the primary antibodies (Bax, PARP, caspase-3, caspase-8 and actin). The membranes were then washed three times (10 min each) with Tween 20 (1:1,000 dilution)-PBS and incubated for 1 h with the appropriate peroxidase-conjugated secondary antibody (1:1,000 dilution; Odyssey Mouse IgG F(c) Antibody IRDye® 800CW Conjugated; LI-COR Biotechnology, Lincoln, NE, USA; cat no. 610-131-003) at 37°C. The membranes were washed three times with Tween 20-PBS (10 min each) and developed using the Odyssey two-color infrared laser imaging system (LI-COR Biosciences, Lincoln, NE, USA). The signal generated by actin was used as an internal control.

Statistical analysis. Statistical analysis was performed using GraphPad Prism 5 (GraphPad Software, Inc., La Jolla, CA, USA). Data are expressed as the mean ± standard deviation and comparisons between two groups were performed using Student's t test. P<0.05 was considered to indicate a statistically significant difference.

Results

Treatment with SK and with ADM decreases cell survival of osteosarcoma cells. The U2OS osteosarcoma cells were treated with different concentrations of ADM, or with 0.1 μ M ADM for different durations. The U2OS cells were also treated with different concentrations of SK for 48 h, or with 0.01 μ M SK for different durations. The results showed that ADM (Fig. 1A and B) and SK (Fig. 1C and D) increased apoptosis of the osteosarcoma cells in a dose- and time-dependent manner.

SK and ADM act synergistically to decrease osteosarcoma cell survival. A CCK-8 assay was used to measure the cell survival rates of the U2OS and MG63 osteosarcoma cells, which were treated with DMEM-h, SK (0.01 μ M), ADM (0.1 μ M), or SK (0.01 μ M) and ADM (0.1 μ M) for 48 h (Fig. 2). The results revealed that SK and ADM acted synergistically to decrease the survival rates of the osteosarcoma cells.

SK enhances the apoptotic effect of ADM in osteosarcoma. The present study further examined differences in cell

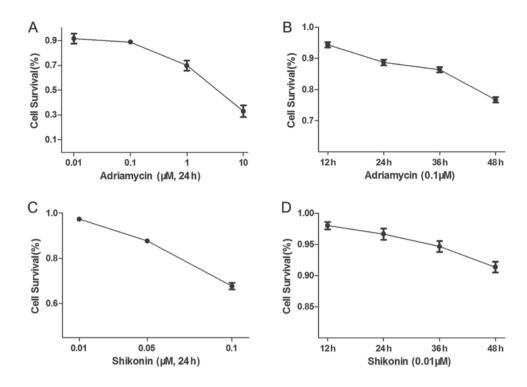

Figure 1. ADM and SK cause increases in apoptosis of osteosarcoma cells. ADM caused a reduction in cell survival of the U2OS cells in a (A) dose-dependent and (B) time-dependent manner. SK caused a reduction in cell survival in a (C) dose-dependent and (D) time-dependent manner. SK, shikonin; aDM, Adriamycin.

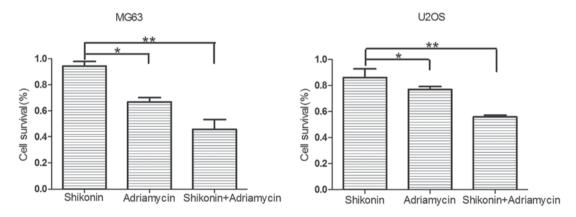

Figure 2. Shikonin and adriamycin act synergistically to increase apoptosis in osteosarcoma cells. *P<0.05; **P<0.01.

apoptosis following treatment of osteosarcoma cells (U2OS and MG63) with SK and/or ADM. The results of the flow cytometric analysis revealed significant increases in cell apoptosis following treatment with SK and ADM for 48 h (Fig. 3). These data suggested that SK induced the apoptotic effects of ADM on the osteosarcoma cells.

SK and ADM promote expression levels of caspase-3 and -8 in osteosarcoma. Caspase-3 and caspase-8 are considered crucial modulators of apoptosis. As shown in Fig. 4, the protein levels of caspase-3 and caspase-8 increased significantly in the U2OS and MG63 cells following treatment with SK and ADM for 48 h at the lowest drug concentrations (P<0.05). The data indicated that SK promoted ADM-induced cell death of the osteosarcoma cells by activating caspase-3- and caspase-8-dependent apoptosis.

Discussion

Osteosarcoma is the most common type of primary malignant tumor of bone and is treated predominantly by surgical resection. However, chemotherapy is important in preoperative and postoperative treatment. Clinical studies have shown that the most commonly used osteosarcoma chemotherapeutic drug, ADM, exhibits an effective rate of only ~40% when used as a single agent (16). The limited efficacy of cytotoxic chemotherapy remains a key obstacle in the treatment of advanced osteosarcoma.

The combined effect of two or more drugs can be superior to that of a single drug in chemotherapy. Combination therapy can increase the rate of tumor cell death and decrease the growth of tumor cells during treatment. As a result, toxic side effects of chemotherapeutic drugs are commonly found in

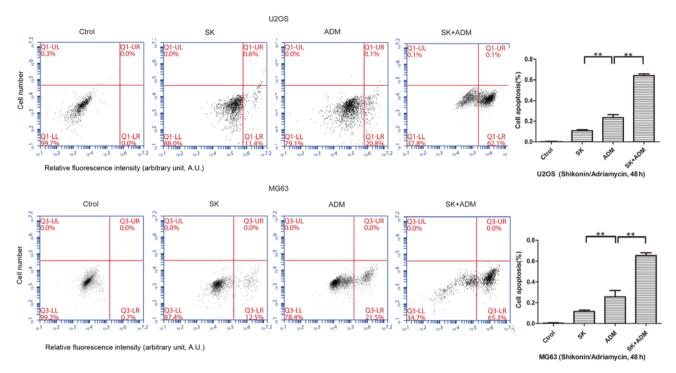

Figure 3. Treatment with SK combined with ADM for 48 h increases osteosarcoma apoptosis. In the U2OS and MG63 cells, apoptosis was significantly higher in the ADM group, compared with the SK group. Apoptosis in the SK+ADM group was higher, compared with that in the SK group. **P<0.01. SK, shikonin; ADM, Adriamycin; Ctrol, control.

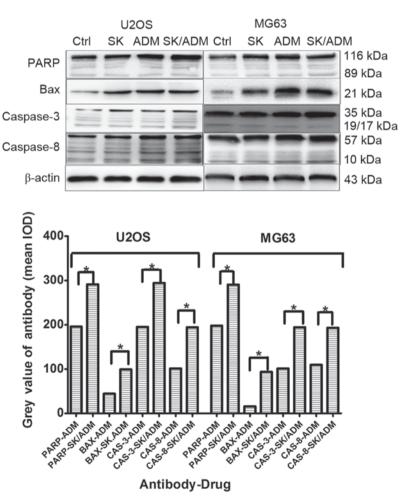

Figure 4. Protein levels of caspase-3 and caspase-8 increase in osteosarcoma cells treated with SK and ADM. Following treatment of the U2OS and MG63 cells with SK and ADM for 48 h, protein levels of caspase-3 and caspase-8 were higher, compared with those in the groups treated with SK or ADM alone. *P<0.05. Ctrl, control; SK, shikonin; ADM, adriamycin; PARP, poly (ADP-ribose) polymerase; BAX, B-cell lymphoma 2-associated X protein.

patients with osteosarcoma. In addition, long-term exposure of the tumor to certain drugs can lead to drug resistance. However, the addition of a second drug markedly reduces the incidence of drug resistance, particularly when the mechanism of drug-induced cell death varies significantly between the two drugs. Drug resistance in cancer is tightly associated with the apoptotic pathway, including the overexpression of anti-apoptotic proteins, mutations in pro-apoptotic proteins and reduction of caspases (17-19). For these reasons, ~40% patients with osteosarcoma do not respond to commonly used anticancer drugs.

ADM is the most commonly used chemotherapeutic drug for the clinical treatment of bone tumors. It exerts antitumor effects by targeting the activity of topoisomerase II (20,21). In addition, ADM is a not a cell cycle-specific drug, being involved in various stages of the cell cycle and inducing cellular apoptosis (22,23). The use of PEGylated liposomal doxorubicin has become a novel treatment strategy for patients with cancer (24). As a traditional chemotherapeutic drug, ADM has inevitable side effects and drug resistance. The treatment of cancer patients with PEGylated liposomal ADM (24) increases drug sensitivity to a certain extent and improves side effects. However, the potential limitations, including the complicated formulation process, potential toxic effects to humans and high medical costs of ADM, have limited the use of liposomal ADM.

As a natural product, SK is important in cancer chemotherapy owing to its beneficial pharmacological activities and low toxicity. SK has also been identified as a cytotoxic DNA-binding agent (14). Furthermore, SK and its analogs have been shown to induce minimal cancer drug resistance (15).

Compared with ADM and its different forms (24), SK has inherent advantages, including being a pure and natural product, showing low toxicity, causing few side effects, exhibiting low drug resistance, being low cost. It also shows high cooperative activity with other anticancer drugs (14,15).

ADM, a classic bone tumor chemotherapeutic drug, and SK, a novel Chinese herb, cooperate in human tumor cell lines and interact to produce apoptotic effects.

In the present study, U2OS and MG63 human tumor cell lines were examined to examine the efficacy of SK in combination with ADM on osteosarcoma. It was found that SK promoted ADM-induced apoptosis at the lowest drug concentrations in osteosarcoma. In addition, SK enhanced the sensitivity of ADM at a low toxicity. Decreases in the required dosage of ADM and expected clinical side effects were observed.

Previous studies (14,15) have shown that SK induces antitumor effects via two major mechanisms: Inducing osteosarcoma necrosis and promoting apoptosis of osteosarcoma cells. Few studies have reported on the use of this drug as a synergistic antitumor agent. Thus, investigating the antitumor mechanism of SK is of important clinical significance.

Caspase-3 and caspase-8 are considered to be crucial modulators of apoptosis (25). In the present study, it was found that the protein levels of caspase-3 and caspase-8 were significantly increased following treatment with SK and ADM at low concentrations in the U2OS and MG63 osteosarcoma cell lines. The levels of Bax and PARP were also significantly increased (26), further validating the apoptotic pathway.

These results indicated that SK induced cell death in U2OS and MG63 osteosarcoma cell lines via the caspase-3- and caspase-8-dependent apoptotic pathway.

In the present study, a potential therapeutic pathway was identified, targeted by SK and ADM to induce apoptosis in osteosarcoma cells. The cooperation of SK with ADM resulted in enhanced apoptosis in osteosarcoma cells via the induction of apoptotic cell death, accompanied by upregulation in the expression levels of caspase-3, caspase-8, Bax and PARP. SK, as a sensitization agent and chemotherapeutic drug, is of clinical value and may serve as a standard for the development of other Chinese herbal medicines. Limitations of the present study include the lack of *in vivo* experiments; therefore, additional investigations using animal models are required in the future.

In conclusion, data obtained in the present study showed that the suppression of growth in osteosarcoma by SK in combination with ADM resulted from the induction of apoptosis *in vitro*. These findings may lead to further investigations on Chinese herbal medicines with unexpected antitumor effects.
