Abstract. The incidence of congenital hypothyroidism (CH) in newborn infants ranges from 1 in 3,000 to 1 in 4,000. Previous studies have indicated the neuroprotective role of microRNA (miR)-124-3p, however the expression and role of miR-124-3p in CH remain unclear. Therefore, the present study was performed to investigate the role and precise molecular mechanism of miR-124-3p in CH. Propylthiouracil (50 mg/day) was injected into the stomach of pregnant rats from gestational day 15 until parturition in order to establish a thyroid hypofunction model. Newborn rats were divided into the following four groups: The control group; the thyroid hypofunction group; the miR-124-3p mimic group; and the miR-124-3p negative control group. Reverse transcription-quantitative polymerase chain reaction indicated that miR-124-3p was significantly decreased in the hippocampus of the thyroid hypofunction group compared with the control group. Bioinformatics software was used to predict mRNA targets recognized by miR-124-3p and the programmed cell death protein 6 (PDCD6) 3' untranslated region (UTR) was demonstrated to exhibit the seed sequence of miR-124-3p. The interaction between miRNA-124-3p and PDCD6 was then verified using a dual-luciferase reporter assay system. PDCD6 expression was significantly increased in the hippocampus of rats with CH compared with the control group. Flow cytometry was performed to investigate the effects of miR-124-3p on neuronal cell apoptosis and the results indicated that the apoptosis rate in the thyroid hypofunction group was significantly increased compared with the control group; this increase was reversed by transfection with miR-124-3p mimics. Western blot analysis was used to detect the levels of cleaved poly [ADP-ribosyl] polymerase (PARP), full-length PARP, caspase-3, B cell lymphoma-2 (Bcl-2) and Bcl-2-associated X protein (Bax) proteins. The results indicated that the expression of cleaved PARP, caspase-3 and Bax protein were significantly increased and the expression of full-length PARP and Bcl-2 protein was significantly decreased compared with the control group. These effects were reversed by miRNA-124-3p mimic transfection. Taken together, the results of the present study demonstrate that miRNA-124-3p serves a protective role in CH via targeting PDCD6.

Introduction

Congenital hypothyroidism (CH) is defined as thyroid hormone deficiency at birth and is one of the most frequent preventable causes of mental retardation; however, the majority of infants with CH do not exhibit obvious clinical manifestations at birth (1). In hypothyroidism, type 2 deiodinase is adapted to increase the conversion of the prohormone thyroxine to the biologically active triiodothyronine (2). Thyroid hormone serves a pivotal role in the development of the mammalian brain and its dyssynthesis, paracrisis or lack of biological effects may be caused by hypothyroidism (3). CH results in various developmental disorders (4). The incidence in newborn infants ranges from 1 in 3,000 to 1 in 4,000 (5) and is markedly higher in preterm compared with full term infants (6).

Previous studies have demonstrated the importance of timely treatment for neurologic outcome, which was indicated by an inverse correlation between intelligence quotient and the age of diagnosis (7,8). Despite early diagnosis of CH, neurologic maldevelopment may also occur when treatment is not optimized in the first 2-3 years of life (9). It is therefore important for patients with CH to receive early treatment and close follow up.

MicroRNAs (miRNAs or miRs) are short non-coding RNAs, which regulate post-transcriptional gene silencing (10). Thousands of miRNAs have been identified in a variety of species (11). Binding of miRNA to the 3' untranslated region (UTR) may degrade target mRNA and block translation (12). Previous studies have suggested the role of miRNAs in nervous system diseases, including autoimmune neuroinflammation (13), Alzheimer's disease (14) and Parkinson's disease (15). miR-124-3p may also attenuate matrix metalloproteinase-induced neuronal injury via regulating signal transducer and activator of transcription 3 expression in SH-SY5Y cells (16). Huang et al (17) suggested
that miR-124-3p may inhibit neuronal inflammation induced by traumatic brain injury and contributes to neurite outgrowth. Furthermore, miR-124-3p serves a neuroprotective role in the 6-hydroxydopamine-induced cell model of Parkinson's disease via regulating ANAX5 (18). miR-124 was also demonstrated to protect neurons from apoptosis in newborn rats with thyroid hypofunction (19). However, the expression and role of miR-124-3p in thyroid hypofunction remains unclear. Therefore, the present study was performed to investigate the role and precise molecular mechanism of miR-124-3p in CH.

Materials and methods

Animal model. A total of 12 pregnant Sprague Dawley rats (body weight, 200±10 g; ~6 week old) were kept in Qingdao Women and Children's Hospital (Shandong, China) in appropriate-sized cages at room temperature and a humidity of 55%. Mice were subjected to a 12 h light/dark cycle and had ad libitum access to standard pellet feed and water. Propylthiouracil (50 mg/day; Beyotime Institute of Biotechnology, Haimen, China) was injected intraperitoneally into pregnant rats at gestational day 15 each day until parturition in order to establish the thyroid hypofunction rat model as previously described (20). Following anesthesia with intraperitoneal injection of 2% pentobarbital sodium (40 mg/kg), newborn rats (12 days old) were fixed on stereotaxic apparatus and their skulls were opened at 1.0 mm from the former fontanel and 1.7 mm from the mid-line. Thereafter, a micro syringe was inserted vertically 3.8 mm at 15 μm/sec and mice were injected with 5 μl 1 nmol/l miR-124-3p mimic solution or miR-124-3p negative control (NC) solution (Shanghai GenePharma Co., Ltd., Shanghai, China) as previously described (21). Newborn rats were divided into the following four groups (each n=5): The control group, the thyroid hypofunction group, the miR-124-3p mimic group and the miR-124-3p NC group. The present study was approved by the Animal Ethics Committee of Qingdao Women and Children's Hospital (Qingdao, China).

Reverse transcription-quantitative polymerase chain reaction (RT-qPCR). At day 15 following birth, newborn rats were sacrificed and the hippocampus was harvested. Total RNA was extracted from the hippocampus using a PrimeScript™ reverse transcription reagent kit (Takara Biotechnology Co., Ltd., Japan) at 4˚C overnight. The first-strand cDNA was synthesized by RT using the following primers: miR-124-3p, forward, 5'-GTC GTA TCC AGT GCA GGG TCC-3' and reverse, 5' -GTG CAG GAC TTT TCA CTT TTG-3'; U6, forward 5' -CTC GCT TCG GCA TAT ATT-3'. PCR was conducted using the following primers: miR-124-3p forward, 5'-AAA ATA TGG AAC GCT TCA CGA ATT TG-3'. PCR was performed in a 20 μl reaction mixture containing 10 μl 2x Master Mix (Thermo Fisher Scientific, Inc.) at 94˚C for 3 min, followed by 40 cycles of 30 sec at 95˚C, 30 sec at 60˚C and 30 sec at 72˚C. Gene expression was normalized to U6 with using the 2^(-∆ΔCq) method (22). This experiment was performed in accordance with a previous study (19).

Cell culture. Neurons were isolated from the hippocampus of rats in the four groups. The cerebral cortices of rats were dissected under an inverted microscope (Olympus Corporation, Tokyo, Japan; magnification: x40). Neurons were seeded in poly-D lysine-coated plates at a concentration of 1x10^6 cells/ml and cultured in Dulbecco's modified Eagle's medium (Gibco; Thermo Fisher Scientific, Inc., Waltham, MA, USA) and 10% fetal bovine serum (Gibco; Thermo Fisher Scientific, Inc.) for 4-6 h at 37˚C. Subsequently, the cell culture medium was replenished with neurobasal medium (Gibco; Thermo Fisher Scientific, Inc.). Neurons were cultured in a incubator at 37˚C in an atmosphere containing 5% CO₂. The culture medium was changed every 3 days.

Transfection with miRNA mimics. Neurons were seeded in 6-well plates (5x10^4 cells per well) and transfected with 50 nM miR-124-3p mimics or 50 nM miR-124-3p negative control (NC; both Shanghai GenePharma Co., Ltd.) using Lipofectamine® 2000 (Thermo Fisher Scientific, Inc.) according to the manufacturer's protocol, following the attainment of 60-70% confluence. After 24 h, neurons were collected for subsequent experiments.

Flow cytometry. Cell apoptosis and the cell cycle were analyzed in the present study using a flow cytometer (FCM; BD Biosciences, Franklin Lakes, NJ, USA). Neurons (1x10^5 cells/well) were digested with 0.025% trypsin, washed with PBS and fixed in 70% cold ethanol at 4˚C overnight. Subsequently, propidium iodide (PI, Sigma Aldrich; Merck KGaA, Darmstadt, Germany), RNaseA and 0.2% Triton X-100 were added to cells and incubated at 4˚C for 30 min in the dark.

Neurons were adjusted to give a concentration of 1x10^6 cells/ml prior to the flow cytometry assay. The cell apoptosis rate was detected at 1 h following the addition of 5 μl fluorescein isothiocyanate-labeled Annexin V and 5 μl PI (cat no. 5692; Cell Signaling Technology, Inc., Danvers, MA, USA). The cell number at each phase was analyzed using FlowJo software 7.6.1 (Tree Star Inc., Ashland, OR, USA).

Western blot analysis. At 24 h post-transfection, neurons were digested with lysis buffer (Cell Signaling Technology, Inc.). Proteins were quantified using a BCA assay (Thermo Fisher Scientific, Inc.) and neurons were cultured in a incubator at 37˚C in an atmosphere containing 5% CO₂. The culture medium was changed every 3 days.

Neurons were lysed with a previous study (19). The cerebral cortices of rats were dissected under an inverted microscope (Olympus Corporation, Tokyo, Japan; magnification: x40). Neurons were seeded in poly-D lysine-coated plates at a concentration of 1x10^6 cells/ml and cultured in Dulbecco's modified Eagle's medium (Gibco; Thermo Fisher Scientific, Inc., Waltham, MA, USA) and 10% fetal bovine serum (Gibco; Thermo Fisher Scientific, Inc.) for 4-6 h at 37˚C. Subsequently, the cell culture medium was replenished with neurobasal medium (Gibco; Thermo Fisher Scientific, Inc.). Neurons were cultured in a incubator at 37˚C in an atmosphere containing 5% CO₂. The culture medium was changed every 3 days.

Transfection with miRNA mimics. Neurons were seeded in 6-well plates (5x10^4 cells per well) and transfected with 50 nM miR-124-3p mimics or 50 nM miR-124-3p negative control (NC; both Shanghai GenePharma Co., Ltd.) using Lipofectamine® 2000 (Thermo Fisher Scientific, Inc.) according to the manufacturer's protocol, following the attainment of 60-70% confluence. After 24 h, neurons were collected for subsequent experiments.

Flow cytometry. Cell apoptosis and the cell cycle were analyzed in the present study using a flow cytometer (FCM; BD Biosciences, Franklin Lakes, NJ, USA). Neurons (1x10^5 cells/well) were digested with 0.025% trypsin, washed with PBS and fixed in 70% cold ethanol at 4˚C overnight. Subsequently, propidium iodide (PI, Sigma Aldrich; Merck KGaA, Darmstadt, Germany), RNaseA and 0.2% Triton X-100 were added to cells and incubated at 4˚C for 30 min in the dark.

Neurons were adjusted to give a concentration of 1x10^6 cells/ml prior to the flow cytometry assay. The cell apoptosis rate was detected at 1 h following the addition of 5 μl fluorescein isothiocyanate-labeled Annexin V and 5 μl PI (cat no. 5692; Cell Signaling Technology, Inc., Danvers, MA, USA). The cell number at each phase was analyzed using FlowJo software 7.6.1 (Tree Star Inc., Ashland, OR, USA).

Western blot analysis. At 24 h post-transfection, neurons were digested with lysis buffer (Cell Signaling Technology, Inc.). Proteins were quantified using a BCA assay (Thermo Fisher Scientific, Inc.). Total protein (25 μg per lane) was separated by 10% SDS-PAGE, transferred to polyvinylidene fluoride membranes and blocked with 5% bovine serum at room temperature for 1.5 h. Membranes were incubated with primary antibodies against caspase-3 (cat. no. 9665), B-cell lymphoma 2 (Bcl-2; cat no. 4223), Bcl-2-associated X protein (Bax; cat no. 5023), cleaved poly ADP-ribose polymerase (PARP; cat. no. 5625) and PARP (cat. no. 9532) (all 1:1,000; all Cell Signaling Technology, Inc.) at 4˚C overnight. β-actin (cat. 22}.
miR-124-3p was downregulated in rats with CH. The results of RT-qPCR indicated that the expression of miR-124-3p was significantly decreased in the hippocampus tissues of rats with CH compared with the control group. Compared with the TH model group, the level of miR-124-3p significantly increased in the hippocampus tissues of CH rats treated with the miR-124-3p mimic. However, no significant differences were identified between the NC and TH groups (Fig. 1).

Bioinformatics analysis. Many potential targets of miR-124-3p were identified, however the PDCD6 3’UTR exhibited the seed sequence of miR-124-3p (Fig. 2A). PDCD6 is a calcium-binding modulator protein, which regulates cell proliferation and apoptosis (23,24), indicating a promising role in CH development. Therefore, PDCD6 was used for subsequent experiments.

miR-124-3p targeted PDCD6 3’UTR. The interaction between miRNA-124-3p and PDCD6 was verified using a dual-luciferase reporter assay system. miRNA-124-3p significantly inhibited the luciferase activity in the PDCD6-wt group but not in the PDCD6-mut group (Fig. 2B).

PDCD6 was upregulated in rats with CH. The results of flow cytometry demonstrated that thyroid hypofunction induced cell apoptosis, which was significantly inhibited by miR-124-3p mimics compared with the control group (Fig. 4). No significant difference in neuronal cell apoptosis was observed between the thyroid hypofunction and miR-124-3p NC groups (Fig. 4). The results of the flow cytometric analysis were confirmed by analyzing PARP cleavage. Cleavage of PARP was significantly increased in the thyroid hypofunction group compared with the control group and this increase was significantly reversed by transfection with miRNA-124-3p mimics. No significant difference in the expression of PARP cleavage in neuronal cells was observed between the thyroid hypofunction group and miR-124-3p NC group (Fig. 5).

miR-124-3p protected neurons from apoptosis. The results of flow cytometry demonstrated that thyroid hypofunction induced cell apoptosis, which was significantly inhibited by miR-124-3p mimics compared with the control group (Fig. 4). No significant difference in neuronal cell apoptosis was observed between the thyroid hypofunction and miR-124-3p NC groups (Fig. 4). The results of the flow cytometric analysis were confirmed by analyzing PARP cleavage. Cleavage of PARP was significantly increased in the thyroid hypofunction group compared with the control group and this increase was significantly reversed by transfection with miRNA-124-3p mimics. No significant difference in the expression of PARP cleavage in neuronal cells was observed between the thyroid hypofunction group and miR-124-3p NC group (Fig. 5).

miR-124-3p reversed the thyroid hypofunction-induced upregulation of caspase-3 and Bax and the downregulation of Bel-2. No significant difference was observed in the expression of caspase-3, Bax and Bcl-2 in neuronal cells between the thyroid hypofunction group and miR-124-3p NC group (Fig. 6). Thyroid hypofunction significantly increased the expression of caspase-3 and Bax proteins, while the expression of Bcl-2 protein was significantly decreased compared with

Figure 1. miR-124-3p was downregulated in rats with CH. Values are expressed as the mean ± standard deviation. Tests were performed in triplicate. *P<0.01 vs. the control group; **P<0.01 vs. the TH group. miR-124-3p, microRNA-124-3p; CH, congenital hypothyroidism; con, the control group; TH, the thyroid hypofunction group; NC, the miR-124-3p NC group; mimic, the miR-124-3p mimics group.
the control group; this effect was reversed by transfection with miRNA-124-3p mimics (Fig. 6).

**Discussion**

The results of the present study indicate that the expression of miR-124-3p was significantly decreased and the expression of PDCD6 was significantly increased in the hippocampus of rats with CH in comparison with the control group. miR-124-3p protected neurons from thyroid hypofunction-induced apoptosis. Thyroid hypofunction induced Caspase-3 and Bax protein expression and reduced Bcl-2 protein expression. However, these changes were eliminated by miR-124-3p via the targeting of PDCD6. In conclusion, it was demonstrated that miRNA-124-3p serves a protective role in CH.

CH is one of the most frequent preventable causes of mental retardation and leads to multiple developmental disorders (4). Despite early diagnosis of CH in infants, neurologic maldevelopment may also occur if treatment is not optimized in the first 2-3 years of life (9). Therefore, it is important for infants to receive optimized treatment.

miRNAs serve a role in nervous system diseases, including autoimmune neuroinflammation (13), Alzheimer's disease (14) and Parkinson's diseases (15). A previous study indicated that the expression of miR-124 was downregulated in newborn rats with thyroid hypofunction (19). However, the target genes of miR-124 remain unknown. Furthermore, as a sub-member of miR-124, the level and role of miR-124-3p in CH remains unclear. Therefore, the present study was performed to investigate the role and precise molecular mechanism of miR-124-3p in CH.

RT-qPCR was performed to investigate changes in the expression of miR-124-3p in CH. The results indicated that miR-124-3p was significantly decreased in the hippocampus of rats with CH compared with the control group, which is consistent with a previous study (19). Bioinformatics analysis was used to predict the possible target genes of miR-124-3p. The PDCD6 3'UTR exhibited the seed sequence of miR-124-3p. The interaction between miRNA-124-3p and PDCD6 was then verified using a dual Luciferase reporter assay system. PDCD6 is a calcium-binding modulator protein that regulates cell proliferation and death (23,24). Aberrant expression of PDCD6 has been observed in various types of human cancer and may act as either an oncogene or a tumor suppressor. For instance, PDCD6 was recently reported to be a tumor suppressor and may be a potential therapeutic target in glioblastoma (25); reintroduction of PDCD6 significantly reverses the effects of miR-183 in enhanced cell cycle/proliferation and inhibits the apoptosis of leukemia cell lines (26); and PDCD6 was highly expressed in metastatic ovarian cancer and induced cell migration/invasion (27). In the present study, RT-qPCR was used to detect the differential expression of PDCD6 in CH and the results indicated that miR-124-3p was significantly increased in the hippocampus of rats with CH compared with the control group. These results were consistent with those of a previous study (27). The results also indicated a negative correlation between miR-124-3p and PDCD6.

It has previously been demonstrated that miR-124 protects neurons against apoptosis in cerebral ischemic stroke (28).
The results of the present study demonstrated that the thyroid hypofunction group had the highest rate of apoptosis, whereas transfection with miR-124-3p mimics significantly decreased this effect, consistent with previous studies (19,28). Apoptosis-associated proteins were further detected in the present study using western blot analysis.

Caspase-3 is a member of the cysteine-aspartic acid protease family, which is encoded by the CASP3 gene (29). Caspase-3 is activated in apoptotic cells by the extrinsic and intrinsic pathways (30). In addition, Bax was the first identified pro-apoptotic member of the Bcl-2 protein family (31) and Bcl-2 itself is an important anti-apoptotic protein (32). In the present study, the protein levels of Caspase-3 and Bax were significantly increased, whereas the expression of Bcl-2 was significantly decreased in the thyroid hypofunction group. These effects were reversed by transfection with miR-124-3p mimics.

In conclusion, the results of the present study demonstrate that miR-124-3p serves a protective role in CH via targeting PDCD6. miR-124-3p may therefore be a potential therapeutic target for the treatment of infants with CH. However, as miR-124-3p has various target genes, the role and underlying mechanism of miR-124-3p in CH progression remain largely unknown. Thus, further study is required to support the conclusions drawn from the present study.
Low thyroid hormone levels improve the progression of Alzheimer's disease.
